

Chapter 1

Introduction

Neutrino oscillation implies that neutrinos have mass, which cannot be currently explained by the Standard Model (SM) due to an absence of right-handed partners to the left-handed neutrinos. Chapter 2 begins with the motivation of a right-handed heavy neutrino state, also referred to as *Heavy Neutral Leptons* (HNLs), that allows for the construction of neutrino mass. An overview of the theoretical model of HNLs is additionally given, covering their productions and decays. The focus is on kinematically allowed channels that can be produced from the Booster Neutrino Beam (BNB) and subsequently decay inside the Short-Baseline Near Detector (SBND).

In the following, a description of the Liquid Argon Time Projection Chamber (LArTPC) is provided in Chapter 3, which is the main detector technology of SBND. The operating principles of an LArTPC are presented, identifying key physical processes of the two main detection signals, ionisation electrons and scintillation photons, that underpin the performance of an LArTPC.

Chapter 4 then provides an overview of the SBND and the BNB. The chapter begins with the physics program of SBND, followed by the detector design, describing each subsystem that comprises the detector. The BNB is discussed next, detailing the beam design and presenting the secondary meson fluxes and neutrino fluxes arriving at SBND.

The simulation framework at SBND is outlined in Chapter 5, to produce Monte Carlo (MC) samples representing data. A description of different generators to simulate SM neutrinos, cosmic muons and HNLs is first provided. The HNL generator is presented in detail to illustrate the physics behind the late arrival of HNLs compared to SM neutrinos produced from the BNB, which the work presented in later chapters relies upon. Finally, the simulation of the particle propagation and the detector response is summarised.

Following that, the reconstruction framework is provided in Chapter 6, covering the reconstruction for each detection subsystem: (1) TPC, (2) Photon Detection System (PDS) and (3) Cosmic Ray Tagger (CRT). Specifically in the TPC reconstruction workflow, an update to an algorithm separating track-like and shower-like reconstructed objects is detailed. An overview of some high-level analysis tools, combining complementary signals from all subsystems, is given next.

Chapter 7 outlines the timing performance of the Data Acquisition (DAQ) at SBND. The chapter begins with a description of the White Rabbit timing system set up to maintain timing synchronisation across different DAQ subsystems. The timing precision of the readout electronics of the CRT and PDS are then accessed, which are the two detection subsystems with timing resolution $\mathcal{O}(1 \text{ ns})$.

Some studies within the scope of charge calibration are discussed in Chapter 8. The first study is on the measurement of electron lifetime, performed on MC samples of anode-to-cathode crossing cosmic muon tracks that fully traverse the detector volume. The second study is to assess the impacts of delta ray fluctuations on recombination, also performed on MC samples with varying delta ray thresholds.

A selection procedure has been developed to select HNLs and reject backgrounds from SM neutrinos and cosmic muons, which will be presented in Chapter 9. Firstly, a signal and background definition is provided, followed by a description of MC samples used to perform the selection. Dedicated cuts for cosmic background SM neutrinos rejection and HNL shower selection are detailed subsequently. The result of the selection is analysed next, identifying the most impactful cuts of the selection. Finally, a study to assess the sensitivity of SBND to HNLs in the case of an improvement in timing reconstruction is presented as a positive outlook of the search for HNLs.

Finally, the capabilities of SBND to search for HNLs are assessed in Chapter 10. The sources and treatments of uncertainties in the analysis are discussed. The procedure used to set upper limits at the 90% confidence level is detailed next. The result of the limit setting is then presented, covering three result projections that can be achieved at SBND. A discussion of the results is finally given, including suggestions for future developments.
